

Equivalent circuit of lithium iron phosphate battery

Overview

Most of the equivalent circuit battery models available in the literature have been developed specifically for one cell and require extensive measurements to calibrate cell electrical parameters in different operation. Lithium-ion batteries are increasingly becoming more important in the energy transition. The data used for the implementation of this generalized model have been collected through a large experimental characterization campaign. The test bench used for lithium-ion. Five LFP cells were experimentally characterized and the data collected from the testing protocols were used both for implementing specific equivalent circuit models for each. The logical steps followed in the development of the generalized LFP model are shown in Fig. 8, in which two main steps can be found: •-. For the validation of the generalized LFP cell model, multi-rate dynamic profiles have been used. These profiles are generated in-house and scaled according to the rate limits and capacity.
